

**METHOD OF DESIGNATING MULTIPLE DIGITAL STREAMS WITHIN A
MULTIPLEXED SIGNAL**

Abstract of the Disclosure

- 5 In a subscriber television system with a host terminal, the present invention allows the
identification of the individual packets from two separate MPEG transport streams that have been
multiplexed together for decoding by a single external conditional access or point-of-deployment
(POD) module. The decoding of individual packets from two separate MPEG transport streams
supports the use of multiple tuner host terminals for such functions as picture-in-picture (PIP)
10 program viewing and the viewing of one program while recording a second program.
